

PERSONA - Fernanda Espinosa - Week 8

Method and limits

Synthetic user in a fresh agent session. Persona: Elena, 46, administrator of a fictional small outpatient clinic in Mexico City. She uses WhatsApp and appointment software, has no cybersecurity expertise, reads ordinary Spanish, is hurried, and worries about sending an incorrect message.

The test used the generated concept mockup and actual HTML/JavaScript text. Chromium was unavailable and its download failed. No actual rendered screenshots were obtained, controls clicked or exports downloaded. This is a concept-and-text walkthrough, not a completed screenshot-based Layer 1 test or real-user study.

Task and sequence

1. Orient: simulated reaction, "I see fictional data and simulated AI. I can practice without sending something accidentally." The real interface labels the exercise and says no message is sent.
2. Choose the inaccessible appointment-system scenario. Actual scenario controls exist in HTML but their rendered usability remains unverified.
3. Read confirmed / unverified / unknown. Elena understands that records access is unknown and cannot say data was stolen or safe.
4. Correct the email to legitimate. The corrected draft now narrows the claim to the email. An apparent contradiction remained: the technical provider was said not to have replied even though they confirmed the email.
5. Set Laura unavailable and Carlos available. Core code picks the backup; both unavailable blocks export. This was code inspection, not browser interaction.
6. Verify fallback channel. Simulated reaction: "Which alternate channel? Is ticking the box enough? The phone is unknown." The original checkbox did not explain verification or specify a channel. This was the worst confusion.
7. Review and approve. Gate requires available approver, checked channel and reviewed text. Current-revision approval enables export eligibility; changes revoke it.
8. Download: handler creates a text file labeled rehearsal, revision, fictional approver and hash. Actual download remains to be tested.
9. Evaluate costs. Simulated reaction: "Price for what? These numbers seem to be for the service seller." Default assumptions calculate MXN 500 margin; ten delivery hours give MXN -1,500. Business-user context needed clarification.

Fixes implemented before second deployment

Worst confusion: added an explicit fictional-channel selector (in-person desk or alternate line from a previously known printed directory). Added instructions to verify through a known source, never from the reported email; explained that the checkbox records the user's check and CLARA does not verify the channel. Changing the channel revokes approval and resets confirmation.

Changed the provider wording to "The response about the interruption is still pending," so legitimate-email verification does not imply investigation completed.

Renamed MONEY LENS to preparation costs and explained that the calculator evaluates the service provider's economics, separately from incident handling.

Retest evidence and remaining work

Eight core mechanical tests pass after the fixes. The synthetic reviewer recommended the wording improvements; no second screenshot-based persona pass is claimed. Next: capture actual screens in sequence, ask a fresh synthetic Elena to attempt the task from those screenshots, document new confusion, then test a real export and mobile layout.

Evidence interpretation

The quotations describe a fictional persona's reactions generated by an AI reviewer. They are design hypotheses, not field findings or proof that a clinic would pay.
